

[0:00–0:12] The problem

"Hi Dr. Reyes- quick update on the baseline model we built to support ED triage decisions. Its job is simple: look at a patient's vitals and complaints, and help flag who needs to be seen immediately."

[0:12–0:28] The metric, in plain words

"The number I care about most isn't how often the model gets things right overall. It's this: *of the patients who truly need resuscitation (ESI Level 1) - how many does the model actually catch?* That's the one number that matters, because that's the group we can't afford to miss."

[0:28–0:44] What it means for a patient

"Right now, if ten ESI Level 1 patients came through the door, our model would correctly flag about three of them. The other seven - patients who need immediate, life-saving care would get sorted into a lower-urgency queue instead. That's a real, dangerous gap."

[0:44–0:60] Honest caveat + next step

"This is a first baseline, not a finished tool, it's not ready for the floor. The next step is tuning the model specifically to catch more of these critical cases, even if that means a few more false alarms on stable patients. I'll have an updated version to show you soon."
