

Unconsidered Metrics

While the vital signs covered in this dataset may provide a strong foundation for emergency triage, there are other important clinical metrics that were not captured that would significantly enhance patient assessment. Blood oxygen saturation (SpO₂) directly complements FiO₂ by showing how effective the lungs are in transferring oxygen into the bloodstream, a patient can have high FiO₂ but poor SpO₂; this signals a serious problem. Blood glucose levels are also important for identifying diabetic emergencies, hypoglycaemia and sepsis. Lactate levels in the blood indicate whether body organs are receiving enough oxygen and are a key marker for sepsis and shock. These additional metrics would give a far more complete picture of patient acuity than vital signs alone.
